1

The present invention relates to a window comprising: a frame having a top member, a bottom member and two side members defining a frame plane, a sash having a top member, a bottom member and two side members defining a sash plane, and a screening arrangement, said sash being connected to the frame by means of at least one hinge connection to provide a hinge axis substantially parallel with the frame top member and the sash top member, such that the sash may be moved from a closed position to a ventilating position, in which ventilating position the sash plane forms an angle within a limited angle range with the frame plane to provide at least one ventilating aperture, said screening arrangement covering said at least one ventilating aperture at least partly in the ventilating position.

Such windows are well known in the art. From AU-B-527915 and DE-A-2622170 it is known to provide a top-hung window, i.e. a window having its hinge axis at the top member of the frame, with an insect screening, which in the ventilating position of the window covers the wedge-shaped ventilating aperture. As the entire sash turns outwards when opening the window, the ventilating aperture may be covered by a single insect screen.

Windows of the pivoting or centre-hung type have found widespread acceptance, especially as roof windows, inter alia because this kind of window facilitates easy window cleaning, as the sash comprising the pane can be turned essentially 180° to allow cleaning of the outside surface of the pane from inside the building. A further advantage of this type of window is that it can be fully opened to a posi-

tion where the sash is turned approximately 90° in which position air inlet is essentially unrestricted.

As the sash turns around a central pivot axis, one half of the sash turns outwards and one half of the sash turns inwards when the window is opened. This characteristic, however, entails some difficulties in the event that the window is to be equipped with a screening arrangement to e.g. restrict access of insects to the interior of the building through the openings between sash and frame when the window is opened.

Over the years different attempts have been made to provide a centre-hung window with a screening arrangement. One such screen is disclosed in US patent No. 2,311,413. This prior art screen is arranged as a screen roller provided in the frame members and connected to the sash members and covers all openings of the window when it is tilted, and hence provides efficient screening of the window in the open position. It is, however, a disadvantage that the screen restricts the movement of the sash, and further, the screen must be disconnected to be able to clean the outside of the window pane, which is hence a somewhat laborious task. Moreover the screen must be removed before the window can be used as an exit, e.g. in case of a fire.

DE-U1-7906434 discloses a centre-hung window with a screen. This prior art screen is of fixed construction conforming to a maximum ventilation opening between frame and sash, i.e. the screen has the shape of a wedge with a cylindrical or approximately cylindrical main surface and a segment, which may be substantially in the form of a sector of a circle or

triangular at each side. The screen may be partly foldable in that it may be hinged to the frame or sash, however, the screen will still be voluminous. As one of the screens at either the top or bottom of 5 the window must be mounted on the inside of the window, this screen will be visible at all times from the inside, which makes this type of screen less advantageous. Further, in the event that the screen is folded away, the screen must be brought into position 10 by reassembling the parts and engaging the parts with the sash and/or frame of the window before the screen is brought to its active position again.

Another screen for a centre-hung window is known from Applicant's US patent No. 5,694,996, which 15 discloses a screening arrangement mounted on the outside of the entire window encapsulating this. The screening arrangement comprises a screen-carrying frame having a first screen covering the window, and sides of a screen material of e.g. bellows shape. The 20 window sash engages the screen-carrying frame forcing the screen-carrying frame outwards in response to the opening of the window. This screening arrangement ensures maximum protection against insects entering through the open window, however, the screening arrangement 25 is of an elaborate design and also restricts light through the window, which in some cases is a drawback.

It is an object of the present invention to provide a window having a screening arrangement, 30 which is discreet and has a minimum influence on the functioning of the window.

To achieve this object the screening arrangement in the window of the kind mentioned in the in-

roduction includes at least one screening element, which, in a closed position of the window, is arranged in a storage position at the interface between frame and sash, and in the ventilating position extends between the frame bottom member and the sash bottom member, and/or between the frame top member and the sash top member, and that each of the screening elements is connected with the sash or frame top or bottom member and is in releasable engagement with the corresponding frame or sash member within said limited angle range. Hereby a window and screening arrangement is obtained in which the screening elements are incorporated very discreetly and with a minimum influence on the functioning of the window. The releasable connection of the screening element and the sash or frame member entails that the screening element can be disconnected easily to enable the window to be operated without the screen.

Furthermore, the window may be of the top-hung, bottom-hung or centre-hung type, as the screening element or elements may be placed at one of or both the top and bottom frame and sash members.

Simple types of screening arrangements can be of a type where each of the screening elements must be operated independently of the sash and manually, according to a preferred embodiment, however, each of the screening elements of the screening arrangement is moved automatically from an inactive position corresponding the closed position of the window to an active position corresponding to the ventilating position, and from the active position to the inactive position when the window is brought from its ventilating position to its closed position. Hereby the

operation of the window and screening arrangement is particularly easy, and the window can thus be operated by anybody without any technical knowledge of the system. Further there is no risk that the operator forgets to employ the screening arrangement or the operator may be too slow, with the attendant risk of e.g. entry of insects.

In an embodiment, which provides a particularly discreet appearance, the screening elements of the screening arrangement may be moved automatically from an active position corresponding to the ventilating position to an inactive position when the window is brought past its ventilating position to a more tilted position of the sash.

According to an embodiment, the screening arrangement includes at least one screening element formed as a flap connected with the top or bottom member of the frame or the sash by means of a hinge. This embodiment has the advantage that such a flap is very easy to install, and it may even be retrofitted to window without any substantial difficulty or amendment of the window construction.

In a simple example the flap is allowed to pivot freely about the hinge, according to a further development of this embodiment, however, said flap is preloaded towards the active position of the screening element by means of a tensioning element such as a coil spring, whereby is achieved with simple means that the flap will abut on the corresponding, opposite frame or sash member, and hence automatically deploy to be active in the ventilating position of the window.

According to an alternative or supplementary

embodiment, the screening arrangement includes at least one screening element formed as a curtain connected with the top or bottom member of the frame or the sash. With this embodiment a screening element is
5 achieved, which has a high flexibility and the provision of a frame for a flexible screening material is rendered superfluous.

The curtain may for example be of a bellow-type, however according to an embodiment said curtain
10 is a roll-up curtain preloaded in the direction of the inactive position of the screening element. With this kind of curtain the inactive position can readily be reached, in particular in case of an automatically activated screening arrangement.

15 According to an alternative embodiment said curtain is a folded curtain, which provides a relatively large screening area, while at the same time providing a screening element requiring a relatively limited storage room.

20 According to an embodiment the screening arrangement includes at least one screening element formed as a slider connected with the top or bottom member of the frame or the sash.

The slider may comprise some sort of screening
25 element, such as a mesh mounted on a frame, however according to a particularly elegant and simple embodiment the slider includes a grid of wires or a plurality of fins or a brush.

The top and bottom members of the sash may be
30 of square or rectangular cross section, but according to an embodiment each of the top and bottom members of the frame and/or sash is provided with a chamfer, whereby is achieved that the opening area between

sash and frame member in the ventilating position is relatively large.

To facilitate the operation of the window and screening arrangement means may be provided for indicating the ventilating position.

In order to maximize the security against entry of insects, sealing means may be provided at each of the side members of the frame and the sash. Preferably, such sealing means comprise a sliding sealing or a brush element.

In a preferred embodiment, screening element or elements are exclusively provided at the top and/or bottom member of the sash and the frame. Surprisingly, it turns out that acceptable ventilation is obtained with a minimum intervention into the sash and frame structure, and with a reduced expenditure with respect to material and manufacturing conditions as compared with prior art windows and screening arrangements. Additionally, this embodiment provides for a particularly discreet and elegant design, the screening element or elements being virtually invisible in the ventilating position as well as in the closed position of the window.

In the following the invention will be described in more detail by way of example and with reference to the drawing, in which

Fig. 1 is a sketch of a window according to the invention,

Fig. 2 is an enlarged view of a screening arrangement of the window of Fig. 1,

Fig. 3 is a view corresponding to Fig. 2 of a screening arrangement according to a second embodiment,

Fig. 4 is a view corresponding to Fig. 2 of a screening arrangement according to a third embodiment,

Fig. 5 corresponds to the embodiment of Fig. 2, 5 with the sash in a more tilted position,

Fig. 6 is a cross section of a screening arrangement according to Fig. 3, in a closed position of the window,

For illustration of the invention the window 1 10 is shown somewhat simplified in Fig. 1. The window 1 comprises a frame 2 having a top member 3, a bottom member 4 and two side members 5, 6 defining a frame plane, and a sash 7 having a top member 8, a bottom member 9 and two side members 10, 11 defining a sash 15 plane. As can be seen the window is, in the embodiment shown, centre-hung in that the sash 7 is connected to the frame 2 by a pivot hinge (not shown) provided between side members 5, 11; 6, 10 of the frame 2 and sash 7, respectively, to be openable by 20 tilting the sash 7 of the window 1 about the hinge axis defined by the pivot hinge. The window 1 is further provided with a screening arrangement 12 comprising a screening element 14 extending between the top members 3, 8 of the frame 2 and sash 7, respectively, and a screening element 13 extending between 25 the bottom members 4, 9 of the frame and sash, respectively. In order to show the principle underlying the invention, the window is shown in a position in which the screening elements at the top and bottom 30 members of the sash and the frame are clearly visible. However, it is noted that the screening arrangement is normally not clearly visible. It is furthermore noted that there is substantially no gap between

the side members of the sash and frame, respectively. In the ventilating position, the sash and frame side members overlap each other such that they provide a sufficient security against entry of e.g. insects at the sides of the window. By a suitable design of the sash and frame it is possible to obtain a sealing co-operation between the respective side members. Such design may e.g. include side members having such dimensions that a snug fit is obtained, or the side members may be formed with grooves and/or shoulder portions to form a labyrinth-seal at the side members.

In order to ensure that the security against entry of insects is improved even further, the window may be provided with sealing means at the side members of the frame and the sash. Such sealing means may be of a kind known, per se, such as e.g. a sliding sealing or a brush element.

The functioning of the screening arrangement is more readily understood based on Fig. 2, which is an enlarged view of the lower part of the window 1. The window is illustrated in a ventilating position, in which the sash 7 is tilted with respect to the frame 2 such that the sash plane forms a limited opening angle with the frame plane. In the ventilating position the screening element 13 covers the opening between the frame bottom member 4 and the sash bottom member 9. As can be seen, there are substantially no openings at the sides of the window in this slightly open position of the window, and hence there is, in many cases, virtually no need for a screen at the sides of the window. However, as described in the above, sealing means may be provided at the side mem-

bers. In this embodiment, the screening element 13 is a flap, which may be connected to the sash by a hinge 13a (not shown in detail) and preloaded in direction of the sash e.g. by a coil spring. The flap 13 may
5 e.g. be connected with the sash bottom member 9 by means of one or more magnets. The flap 13 is thus moved from an inactive position, in which it rests on the inner surface 9a of the sash bottom member 9, to an active position, in which the end of the flap 13
10 opposite the hinge 13a is brought into abutment with the frame bottom member 4. It should be noted that the flap may as well be connected with the frame member, as long as the screening element is accommodated at the interface between the sash and the frame in
15 its storage position. In this connection, it should furthermore be noted that the term "interface" should be interpreted in a broad sense, i.e. as encompassing the area at or near the surfaces facing each other. In the embodiment of Fig. 2, this area thus comprises
20 e.g. the lower surfaces 9a and the adjacent border portions of the outer and inner surfaces. Further, screening element 13 may be a folded flap, to thereby provide a screen having a larger screening area and/or a screen requiring a reduced storage area.

25 As is also apparent from Fig. 2, the sash bottom member 9 is provided with a chamfer, such that the lower surface 9a forms an angle with respect to the outer and inner surfaces. Hereby, a larger ventilating aperture is obtained. In order to eliminate or
30 at least reduce the need for sealing means at the side members, the side members should be substantially planar.

An alternative embodiment of the screening ar-

5 rangement can be seen in Fig. 3, which is an enlarged view of the lower part of the window 1. Again the window is illustrated in a ventilating position, in which a screening element 23 covers the opening between the frame bottom member 4 and the sash bottom member 9. In this embodiment, the screening element 13 is a curtain in the form of a roller screen comprising a roller 25, which may be housed in the sash bottom member 9 as shown or in the frame bottom member 4. The screening element 23 is connected to the opposite bottom member, i.e. to the frame bottom member 4 in the embodiment shown. The roller 25 may be preloaded to a storage position in which virtually the whole screening element 23 is rolled up on the 15 roller 25.

A third embodiment of the screening arrangement can be seen in Fig. 4, which is an enlarged view of the lower part of the window 1. Again the window is illustrated in a ventilating position, in which the 20 screening element 33 covers the opening between the frame bottom member 4 and the sash bottom member 9. In this embodiment, the screening element 33 is a slider of fins, lamella or a mesh protruding from the sash bottom member 9 and hence screening the opening 25 between the sash bottom member 9 and the frame bottom member 4. It is preferred that the slider is preloaded or biased in direction of the inactive, retracted position, where the slider is stored in the sash bottom member 9. Alternatively the slider may be 30 preloaded or biased in direction of the active, protruding position, where the slider constitutes a screen covering the opening between the frame and sash. As will be clear to the skilled person, the

slider can also be housed in the frame bottom member 4. The slider may be formed by an element having itself a sufficient length in order to bridge the gap between the corresponding sash and frame members in the ventilating position, or it may be formed as a set of mutually displaceable and connected elements such that a telescopic configuration is obtained.

Common to the embodiments shown in Figs. 2-4 is that the screening element 13, 23, 33 only covers the opening between the sash and frame up to a limited opening angle of the sash, i.e. in a ventilating position of the window, whereas the screening element disengages from one of the frame or sash members when the opening angle of the sash exceeds this limited opening angle, thereby allowing practically unrestricted airflow through the openings between the sash and the frame. This is illustrated in Fig. 5, which correspond to the embodiment of Fig. 2, where the sash is tilted past the limited opening angle. In this position, the flap constituting the screening element 13 in this embodiment is disengaged from the bottom frame member 4, and preferably pivoted to a storage position in abutment with the inner surface 9a underneath the sash bottom member 9, as shown. As previously mentioned the flap may be preloaded towards said storage position, such that the flap will automatically pivot to this storage position when the sash is tilted past the limited opening angle. Alternatively the flap may be pivoted and fixed in the storage position manually, or the flap may be allowed to hang from the sash bottom member 9.

Fig. 6 corresponds to the embodiment of Fig. 3, however in a closed position of the window. The

roller 25 is housed in the sash bottom member 9, and in this position of the sash most of the screening element 23 is rolled onto the roller 25. As schematically shown, the end of the screening element 23 is
5 connected to the frame bottom member 4 by an engagement means 26, such as some kind of snap lock or a magnet. The engagement means 26 is adapted to hold the end of the screening element 23 until the sash is tilted so much that all the screen material has been
10 unwound from the roller 14, corresponding to the limited opening angle. Further, the engagement means is adapted to allow disengagement of the screen from the frame bottom member 4, while on the other hand providing a perceptible resistance to disengagement when
15 the sash is tilted past the limited opening angle of the ventilation position. By providing a perceptible resistance to disengagement, the user is informed that the screen is disengaged. It is preferred that the engagement means will automatically reconnect
20 when the window is fully closed again, so the screen is ready for operation when the window is opened. The schematically illustrated engagement means 26 is solely an example and other embodiments are possible, such as a hook and latch mechanism or the like.

25 Again it will be evident to the skilled person that a similar screening arrangement and engagement means may be provided at the upper part of the window, and that the screening arrangement may be provided at the frame instead of at the sash.

30 The description above is only an example, and it will be evident to the skilled person that the inventive principle can also find application on e.g. top-hung windows.

C L A I M S

1. A window (1) comprising:

a frame (2) having a top member (3), a bottom member (4) and two side members (5, 6) defining a frame plane,

a sash (7) having a top member (8), a bottom member (9) and two side members (10, 11) defining a sash plane, and

a screening arrangement (12),

10 said sash (7) being connected to the frame (2) by means of at least one hinge connection to provide a hinge axis substantially parallel with the frame top member (3) and the sash top member (8), such that the sash (7) may be moved from a closed position to a ventilating position, in which ventilating position the sash plane forms an angle within a limited angle range with the frame plane to provide at least one ventilating aperture, said screening arrangement (12) covering said at least one ventilating aperture at
15
20 least partly in the ventilating position,

c h a r a c t e r i z e d in that

the screening arrangement (12) includes at least one screening element (13, 23, 33), which, in a closed position of the window (1), is arranged in a storage position at the interface between frame (2) and sash (7), and in the ventilating position extends between the frame bottom member (4) and the sash bottom member (9), and/or between the frame top member (3) and the sash top member (8), and that each of the
25
30 screening elements (13, 23, 33) is connected with the sash or frame top or bottom member (8, 3, 9, 4) and is in releasable engagement with the corresponding frame (3, 4) or sash member (8, 9) within said lim-

ited angle range.

2. A window (1) as claimed in claim 1, wherein each of the screening elements (13, 23, 33) of the screening arrangement (12) is moved automatically
5 from an inactive position corresponding the closed position of the window to an active position corresponding to the ventilating position, and from the active position to the inactive position when the window is brought from its ventilating position to
10 its closed position.

3. A window (1) as claimed in any one of claims 1 or 2, wherein each of the screening elements (13, 23, 33) of the screening arrangement (12) is moved automatically from an active position corresponding
15 to the ventilating position to an inactive position when the window is brought past its ventilating position to a more tilted position of the sash (7).

4. A window (1) as claimed in any one of claims 1-3, wherein the screening arrangement (12) includes
20 at least one screening element (13) formed as a flap connected with the top or bottom member of the frame (3, 4) or the sash (8, 9) by means of a hinge.

5. A window (1) as claimed in claim 4, wherein said flap is preloaded towards the active position of
25 the screening element (13) by means of a tensioning element such as a coil spring.

6. A window (1) as claimed in any one of claims 1-3, wherein the screening arrangement (12) includes at least one screening element (23) formed as a cur-
30 tain connected with the top or bottom member of the frame or the sash.

7. A window (1) as claimed in claim 6, wherein said curtain is a roll-up curtain preloaded in the

direction of the inactive position of the screening element (12).

8. A window (1) as claimed in claim 6, wherein said curtain is a folded curtain.

5 9. A window (1) as claimed in any one of claims 1-3, wherein the screening arrangement includes at least one screening element (33) formed as a slider connected with the top or bottom member of the frame or the sash.

10 10. A window (1) as claimed in claim 9, wherein the slider includes a grid of wires or a plurality of fins or a brush.

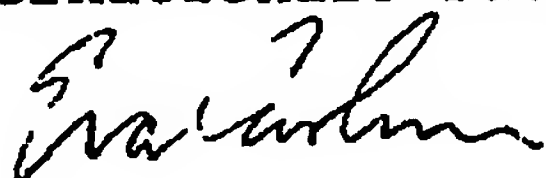

11. A window (1) as claimed in any one of the preceding claims, wherein each of the top and bottom 15 members of the frame and/or sash is provided with a chamfer.

12. A window (1) as claimed in any one of preceding claims, wherein means are provided for indicating the ventilating position.

20 13. A window (1) as claimed in any one of the preceding claims, wherein sealing means are provided at each of the side members of the frame and sash.

14. A window (1) as claimed in claim 13, wherein said sealing means comprise a sliding sealing 25 or a brush element.

15. A window (1) as claimed in any one of the preceding claims, wherein said at least one screening element is provided exclusively at the top and/or bottom member of the sash and the frame.

Window with screening arrangement

5

A B S T R A C T

The window (1) comprises a frame (2) having a top member (3), a bottom member (4) and two side members (5, 6), and a sash (7) having a top member (8), a bottom member (9) and two side members (10, 11). A screening arrangement (12) is provided in order to cover the ventilating aperture at least partly in the ventilating position. To achieve a discreet screening arrangement having minimum influence on the functioning of the window, the screening arrangement (12) includes at least one screening element (13, 23, 33), which, in a closed position of the window (1), is arranged in a storage position at the interface between frame (2) and sash (7), and in the ventilating position extends between the frame bottom member (4) and the sash bottom member (9), and/or between the frame top member (3) and the sash top member (8). Each of the screening elements (13, 23, 33) is connected with the sash or frame top or bottom member (8, 3, 9, 4) and is in releasable engagement with the corresponding frame (3, 4) or sash member (8, 9) within the limited angle range.
